## Last Class: Naming

- Name distribution: use hierarchies
- DNS
- X. 500 and LDAP

## Canonical Problems in Distributed Systems

- Time ordering and clock synchronization
- Leader election
- Mutual exclusion
- Distributed transactions
- Deadlock detection

## Clock Synchronization

- Time in unambiguous in centralized systems
- System clock keeps time, all entities use this for time
- Distributed systems: each node has own system clock
- Crystal-based clocks are less accurate (1 part in million)
- Problem: An event that occurred after another may be assigned an earlier time

## Physical Clocks: A Primer

- Accurate clocks are atomic oscillators (one part in $10^{13}$ )
- Most clocks are less accurate (e.g., mechanical watches)
- Computers use crystal-based blocks (one part in million)
- Results in clock drift
- How do you tell time?
- Use astronomical metrics (solar day)
- Coordinated universal time (UTC) - international standard based on atomic time
- Add leap seconds to be consistent with astronomical time
- UTC broadcast on radio (satellite and earth)
- Receivers accurate to 0.1 - 10 ms
- Need to synchronize machines with a master or with one another

## Clock Synchronization

## - Each clock has a maximum drift rate $\rho$

- $1-\rho<=\mathrm{dC} / \mathrm{dt}<=1+\rho$
- Two clocks may drift by $2 \rho \Delta \mathrm{t}$ in time $\Delta \mathrm{t}$
- To limit drift to $\delta=>$ resynchronize every $\delta / 2 \rho$ seconds

## Cristian's Algorithm

-Synchronize machines to a time server with a UTC receiver

- Machine P requests time from server every $\delta / 2 \rho$ seconds
- Receives time $t$ from server, P sets clock to $t+t_{\text {reply }}$ where $t_{\text {reply }}$ is the time to send reply to $P$
$-\operatorname{Use}\left(t_{\text {req }}+t_{\text {reply }}\right) / 2$ as an estimate of $t_{\text {reply }}$
- Improve accuracy by making a process $P$ series of measurements

## Berkeley Algorithm

- Used in systems without UTC receiver
- Keep clocks synchronized with one another
- One computer is master, other are slaves
- Master periodically polls slaves for their times
- Average times and return differences to slaves
- Communication delays compensated as in Cristian's algo
- Failure of master => election of a new master

## Berkeley Algorithm

a) The time daemon asks all the other machines for their clock values
b) The machines answer
c) The time daemon tells everyone how to adjust their clock

## Distributed Approaches

- Both approaches studied thus far are centralized
- Decentralized algorithms: use resync intervals
- Broadcast time at the start of the interval
- Collect all other broadcast that arrive in a period $S$
- Use average value of all reported times
- Can throw away few highest and lowest values
- Approaches in use today
- rdate: synchronizes a machine with a specified machine
- Network Time Protocol (NTP)
- Uses advanced techniques for accuracies of 1-50 ms

## Logical Clocks

- For many problems, internal consistency of clocks is important
- Absolute time is less important
- Use logical clocks
- Key idea:
- Clock synchronization need not be absolute
- If two machines do not interact, no need to synchronize them
- More importantly, processes need to agree on the order in which events occur rather than the time at which they occurred

## Event Ordering

- Problem: define a total ordering of all events that occur in a system
- Events in a single processor machine are totally ordered
- In a distributed system:
- No global clock, local clocks may be unsynchronized
- Can not order events on different machines using local times
- Key idea [Lamport ]
- Processes exchange messages
- Message must be sent before received
- Send/receive used to order events (and synchronize clocks)

## Happened Before Relation

- If $A$ and $B$ are events in the same process and $A$ executed before $B$, then $A->B$
- If $A$ represents sending of a message and $B$ is the receipt of this message, then A -> B
- Relation is transitive:
- A -> B and B -> C => A -> C
- Relation is undefined across processes that do not exhange messages
- Partial ordering on events

## Event Ordering Using HB

- Goal: define the notion of time of an event such that
- If A-> B then $\mathrm{C}(\mathrm{A})<\mathrm{C}(\mathrm{B})$
- If A and B are concurrent, then $\mathrm{C}(\mathrm{A})<,=$ or $>\mathrm{C}(\mathrm{B})$
- Solution:
- Each processor maintains a logical clock $\mathrm{LC}_{\mathrm{i}}$
- Whenever an event occurs locally at $\mathrm{I}, \mathrm{LC}_{\mathrm{i}}=\mathrm{LC}_{\mathrm{i}}+1$
- When $i$ sends message to $j$, piggyback $\operatorname{Lc}_{\mathrm{i}}$
- When $j$ receives message from $i$
- If $\mathrm{LC}_{\mathrm{j}}<\mathrm{LC}_{\mathrm{i}}$ then $\mathrm{LC}_{\mathrm{j}}=\mathrm{LC}_{\mathrm{i}}+1$ else do nothing
- Claim: this algorithm meets the above goals

## Lamport's Logical Clocks

(a)

(b)

## Example: Totally-Ordered Multicasting
