Processes and Threads

- Processes and their scheduling
- Multiprocessor scheduling
- Threads
- Distributed Scheduling/migration

Processes: Review

- Multiprogramming versus multiprocessing
- Kernel data structure: process control block (PCB)
- Each process has an address space
  - Contains code, global and local variables..
- Process state transitions
- Uniprocessor scheduling algorithms
  - Round-robin, shortest job first, FIFO, lottery scheduling, EDF
- Performance metrics: throughput, CPU utilization, turnaround time, response time, fairness
Process Behavior

- Processes: alternate between CPU and I/O
- CPU bursts
  - Most bursts are short, a few are very long (high variance)
  - Modeled using hyperexponential behavior
  - If $X$ is an exponential r.v.
    - $\Pr [ X <= x] = 1 - e^{-\mu x}$
    - $E[X] = 1/\mu$
  - If $X$ is a hyperexponential r.v.
    - $\Pr [X <= x] = 1 - p e^{-\mu_1 x} -(1-p) e^{-\mu_2 x}$
    - $E[X] = p/ \mu_1 + (1-p)/ \mu_2$

Process Scheduling

- Priority queues: multiples queues, each with a different priority
  - Use strict priority scheduling
  - Example: page swapper, kernel tasks, real-time tasks, user tasks
- Multi-level feedback queue
  - Multiple queues with priority
  - Processes dynamically move from one queue to another
    - Depending on priority/CPU characteristics
  - Gives higher priority to I/O bound or interactive tasks
  - Lower priority to CPU bound tasks
  - Round robin at each level
Processes and Threads

• Traditional process
  – One thread of control through a large, potentially sparse address space
  – Address space may be shared with other processes (shared mem)
  – Collection of systems resources (files, semaphores)

• Thread (light weight process)
  – A flow of control through an address space
  – Each address space can have multiple concurrent control flows
  – Each thread has access to entire address space
  – Potentially parallel execution, minimal state (low overheads)
  – May need synchronization to control access to shared variables

Threads

• Each thread has its own stack, PC, registers
  – Share address space, files,…
Why use Threads?

• Large multiprocessors need many computing entities (one per CPU)
• Switching between processes incurs high overhead
• With threads, an application can avoid per-process overheads
  – Thread creation, deletion, switching cheaper than processes
• Threads have full access to address space (easy sharing)
• Threads can execute in parallel on multiprocessors

Why Threads?

• Single threaded process: blocking system calls, no parallelism
• Finite-state machine [event-based]: non-blocking with parallelism
• Multi-threaded process: blocking system calls with parallelism
• Threads retain the idea of sequential processes with blocking system calls, and yet achieve parallelism
• Software engineering perspective
  – Applications are easier to structure as a collection of threads
    • Each thread performs several [mostly independent] tasks
Multi-threaded Clients Example: Web Browsers

- Browsers such as IE are multi-threaded
- Such browsers can display data before entire document is downloaded: performs multiple simultaneous tasks
  - Fetch main HTML page, activate separate threads for other parts
  - Each thread sets up a separate connection with the server
    - Uses blocking calls
  - Each part (gif image) fetched separately and in parallel
  - Advantage: connections can be setup to different sources
    - Ad server, image server, web server…

Multi-threaded Server Example

- Apache web server: pool of pre-spawned worker threads
  - Dispatcher thread waits for requests
  - For each request, choose an idle worker thread
  - Worker thread uses blocking system calls to service web request
Thread Management

- Creation and deletion of threads
  - Static versus dynamic
- Critical sections
  - Synchronization primitives: blocking, spin-lock (busy-wait)
  - Condition variables
- Global thread variables
- Kernel versus user-level threads

User-level versus kernel threads

- **Key issues:**
- Cost of thread management
  - More efficient in user space
- Ease of scheduling
- Flexibility: many parallel programming models and schedulers
- Process blocking – a potential problem
User-level Threads

- Threads managed by a threads library
  - Kernel is unaware of presence of threads
- Advantages:
  - No kernel modifications needed to support threads
  - Efficient: creation/deletion/switches don’t need system calls
  - Flexibility in scheduling: library can use different scheduling algorithms, can be application dependent
- Disadvantages
  - Need to avoid blocking system calls [all threads block]
  - Threads compete for one another
  - Does not take advantage of multiprocessors [no real parallelism]
Kernel-level threads

- Kernel aware of the presence of threads
  - Better scheduling decisions, more expensive
  - Better for multiprocessors, more overheads for uniprocessors

Light-weight Processes

- Several LWPs per heavy-weight process
- User-level threads package
  - Create/destroy threads and synchronization primitives
- Multithreaded applications – create multiple threads, assign threads to LWPs (one-one, many-one, many-many)
- Each LWP, when scheduled, searches for a runnable thread \textit{[two-level scheduling]}
  - Shared thread table: no kernel support needed
- When a LWP thread block on system call, switch to kernel mode and OS context switches to another LWP
LWP Example

![Diagram](image)

**Thread Packages**

- **Posix Threads (pthreads)**
  - Widely used threads package
  - Conforms to the Posix standard
  - Sample calls: pthread_create,…
  - Typical used in C/C++ applications
  - Can be implemented as user-level or kernel-level or via LWPs

- **Java Threads**
  - Native thread support built into the language
  - Threads are scheduled by the JVM
