

Today: Canonical Problems in Distributed Systems

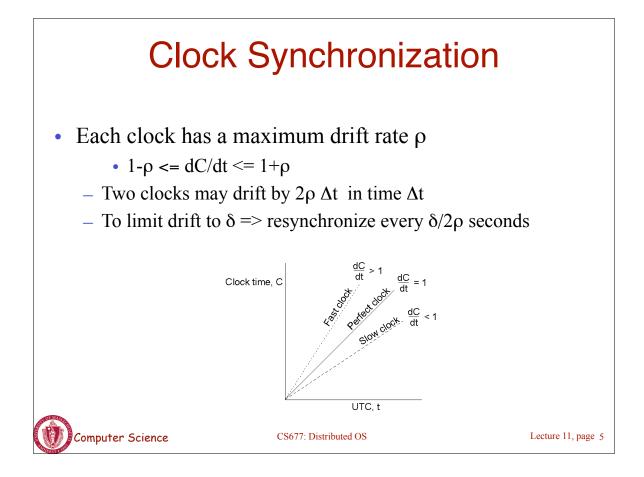

- Time ordering and clock synchronization
- Leader election
- Mutual exclusion
- Distributed transactions
- Deadlock detection

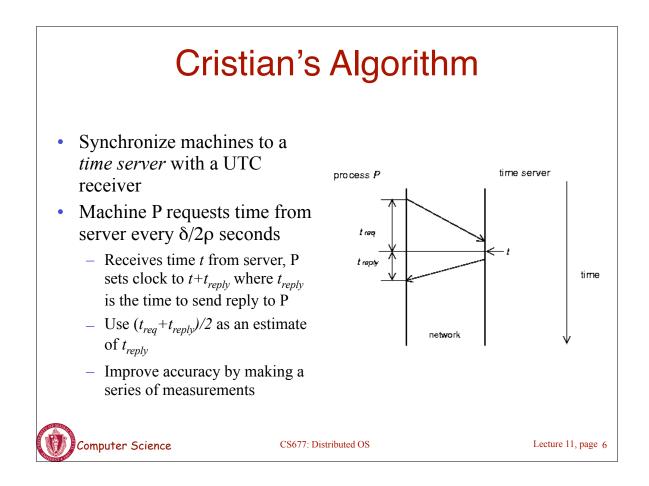

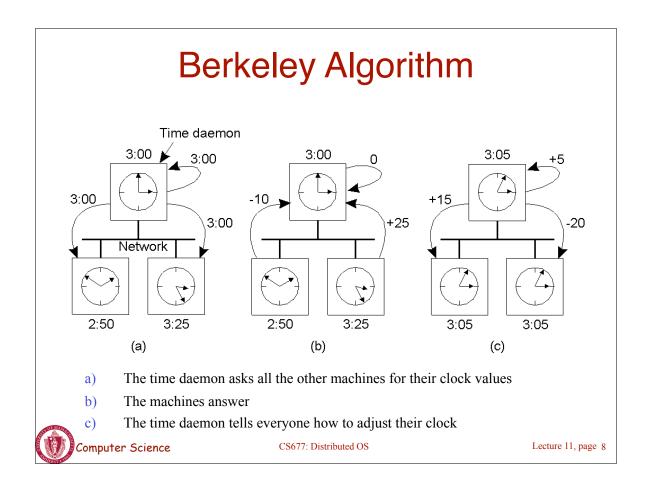

Physical Clocks: A Primer

- Accurate clocks are atomic oscillators (one part in 10¹³)
- Most clocks are less accurate (e.g., mechanical watches)
 - Computers use crystal-based blocks (one part in million)
 - Results in *clock drift*
- How do you tell time?
 - Use astronomical metrics (solar day)
- Coordinated universal time *(UTC)* international standard based on atomic time
 - Add leap seconds to be consistent with astronomical time
 - UTC broadcast on radio (satellite and earth)
 - Receivers accurate to 0.1 10 ms
- Need to synchronize machines with a master or with one another

Distributed Approaches

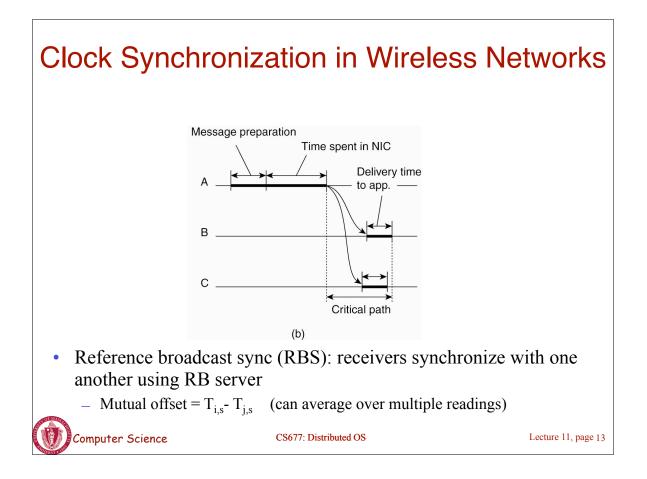

- Both approaches studied thus far are centralized
 Decentralized algorithms: use resync intervals

 Broadcast time at the start of the interval
 Collect all other broadcast that arrive in a period S
 - Use average value of all reported times
 - Can throw away few highest and lowest values
 - Approaches in use today
 - *rdate*: synchronizes a machine with a specified machine
 - Network Time Protocol (NTP) discussed in a later slide
 - Uses advanced techniques for accuracies of 1-50 ms

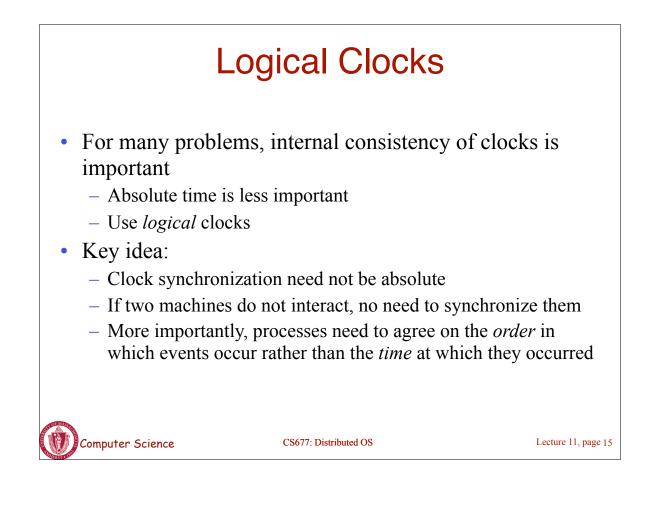

- *Problem:* define a total ordering of all events that occur in a system
- Events in a single processor machine are totally ordered
- In a distributed system:
 - No global clock, local clocks may be unsynchronized
 - Can not order events on different machines using local times
- Key idea [Lamport]
 - Processes exchange messages
 - Message must be sent before received
 - Send/receive used to order events (and synchronize clocks)
