Today: More Classical Problems

- Part 1: Leader election
- Part 2: Mutual exclusion

Lec. 14 1

Part 1: Election Algorithms

- · Many distributed algorithms need one process to act as coordinator
 - Doesn't matter which process does the job, just need to pick one
- Election algorithms: technique to pick a unique coordinator (aka *leader election*)
- Examples: take over the role of a failed process, pick a master in Berkeley clock synchronization algorithm
- Types of election algorithms: Bully and Ring algorithms

Bully Algorithm

- · Each process has a unique numerical ID
- · Processes know the Ids and address of every other process
- · Communication is assumed reliable
- Key Idea: select process with highest ID
- · Process initiates election if it just recovered from failure or if coordinator failed
- 3 message types: election, OK, I won
- · Several processes can initiate an election simultaneously
 - Need consistent result
- O(n²) messages required with n processes

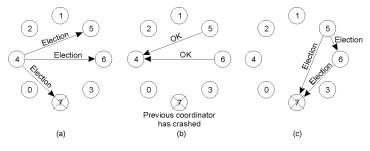

Lec. 14 3

Bully Algorithm Details

- Any process *P* can initiate an election
- *P* sends *Election* messages to all process with higher lds and awaits *OK* messages
- If no *OK* messages, *P* becomes coordinator and sends *I* won messages to all process with lower lds
- If it receives an OK, it drops out and waits for an I won
- If a process receives an *Election* msg, it returns an *OK* and starts an election
- If a process receives a *I won*, it treats sender an coordinator

Bully Algorithm Example

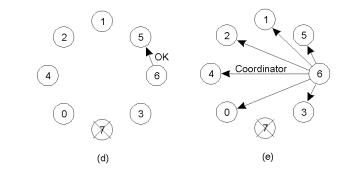

- The bully election algorithm
- Process 4 holds an election
- Process 5 and 6 respond, telling 4 to stop
- Now 5 and 6 each hold an election

Lec. 14 5

Bully Algorithm Example

- d) Process 6 tells 5 to stop
- e) Process 6 wins and tells everyone

Ring-based Election

- · Processes have unique Ids and arranged in a logical ring
- Each process knows its neighbors
 - Select process with highest ID
- · Begin election if just recovered or coordinator has failed
- Send Election to closest downstream node that is alive
 - Sequentially poll each successor until a live node is found
- · Each process tags its ID on the message
- · Initiator picks node with highest ID and sends a coordinator message
- Multiple elections can be in progress
 - Wastes network bandwidth but does no harm

A Ring Algorithm

6

5

[5]

No response

4

• Election algorithm using a ring.

Lec. 14 8

Comparison

- Assume *n* processes and one election in progress
- Bully algorithm
 - Worst case: initiator is node with lowest ID
 - Triggers n-2 elections at higher ranked nodes: O(n²) msgs
 - Best case: immediate election: n-2 messages
- Ring
 - 2 (n-1) messages always

Lec. 14 9

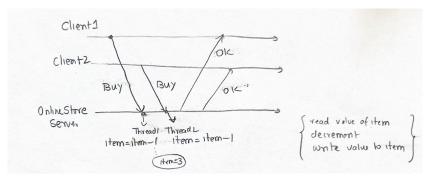

Part 2: Distributed Synchronization

- Distributed system with multiple processes may need to share data or access shared data structures
 - Use critical sections with mutual exclusion
- · Single process with multiple threads
 - Semaphores, locks, monitors
- · How do you do this for multiple processes in a distributed system?
 - Processes may be running on different machines
- · Solution: lock mechanism for a distributed environment
 - Can be centralized or distributed

Lock Example

- Online store example:
 - · 2 clients buy same item, need to decrement stock

University of Massachusetts Amherst

Lec. 14 11

Centralized Mutual Exclusion

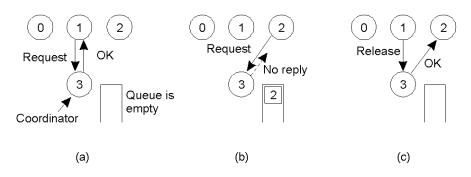

· Assume processes are numbered

Compsci 677: Distributed and OS

- One process is elected coordinator (highest ID process)
- · Every process needs to check with coordinator before entering the critical section
- To obtain exclusive access: send request, await reply
- To release: send release message
- Coordinator:
 - Receive request: if available and queue empty, send grant; if not, queue request
 - Receive release: remove next request from queue and send grant

Mutual Exclusion: A Centralized Algorithm

- a) Process 1 asks the coordinator for permission to enter a critical region. Permission is granted
- b) Process 2 then asks permission to enter the same critical region. The coordinator does not reply.
- c) When process 1 exits the critical region, it tells the coordinator, when then replies to 2

University of Massachusetts Amherst

Lec. 14 13

Properties

- · Simulates centralized lock using blocking calls
- · Fair: requests are granted the lock in the order they were received
- Simple: three messages per use of a critical section (request, grant, release)
- · Shortcomings:
 - Single point of failure
 - How do you detect a dead coordinator?
 - · A process can not distinguish between "lock in use" from a dead coordinator
 - No response from coordinator in either case
 - Performance bottleneck in large distributed systems

Decentralized Algorithm

- Use voting
- · Assume n replicas and a coordinator per replica
- To acquire lock, need majority vote m > n/2 coordinators
 - Non blocking: coordinators returns OK or "no"
- Coordinator crash => forgets previous votes
 - Probability that k coordinators crash $P(k) = {}^{m}C_{k} p^{k} (1-p)^{m-k}$
 - Atleast 2m-n need to reset to violate correctness
 - ∑ _{2m-n} ⁿP(k)

University of Massachusetts Amherst

Distributed Algorithm

- [Ricart and Agrawala]: needs 2(n-1) messages
- Based on event ordering and time stamps
 - Assumes total ordering of events in the system (Lamport's clock)
- Process k enters critical section as follows
 - Generate new time stamp $TS_k = TS_k + I$
 - Send request(k, TSk) all other n-1 processes
 - Wait until reply(j) received from all other processes
 - Enter critical section
- Upon receiving a request message, process j
 - Sends reply if no contention
 - If already in critical section, does not reply, queue request
 - If wants to enter, compare TS_j with TS_k and send reply if $TS_k < TS_j$, else queue (recall: total ordering based on multicast)

Lec. 14 15

Properties

- · Fully decentralized
- N points of failure!
- All processes are involved in all decisions -Any overloaded process can become a bottleneck

Lec. 14 17

A Token Ring Algorithm $1 \bigcirc 5 \bigcirc 3$ 6 (a) (b) a) An unordered group of processes on a network.

- b) A logical ring constructed in software.
- Use a token to arbitrate access to critical section •
- Must wait for token before entering CS •
- Pass the token to neighbor once done or if not interested
- Detecting token loss in non-trivial

Comparison

Algorithm	Messages per entry/ exit	Delay before entry (in message times)	Problems
Centralized	3	2	Coordinator crash
Decentralized	3mk	2m	starvation
Distributed	2(n-1)	2 (n – 1)	Crash of any process
Token ring	1 to ∞	0 to n – 1	Lost token, process crash

• A comparison of four mutual exclusion algorithms.

University of Massachusetts Amherst

Lec. 14 19

Chubby Lock Service

- · Chubby: distributed lock service developed by google
 - · Design for coarse-grain locking
 - · uses file system abstraction for locks
 - · Each Chubby cell (~5 machines) supports 10,000 servers
 - · One replica is outside the data center for high availability
 - · distributed file system interface for locking and sharing state
- Use cases:
 - · Leader election: use locks for leader election and advertise leader
 - · Grab lock, declare oneself leader
 - · Coarse-grain synchronization hold lock for hours or days

Chubby Lock Service

- Chubby cell: elect a primary
 - · each replica maintains a DB
 - · master initiates updates to DB
- Use file abstraction
 - file is a "named" lock
 - reader-writer locks
- Primary can fail

• Triggers new election
